■ “*Intelligence*”

- What is intelligence?
- How can intelligence be measured?
- How does our brain work?
- Intelligent machine (that behaves like a person, showing intelligent behavior)?

■ “*Artificial*”

- Science fiction? Fears of intelligent cyborgs?
- Rebuild human mind?
- Philosophy, e.g. mind-body dualism?

What is Artificial Intelligence (AI)?

John McCarthy (1955)

The goal of AI is to develop machines that behave as though they were intelligent.

Figure: Two very simple Braitenberg vehicles and their reactions to a light source.

- Braitenberg vehicles: two wheels, each of which is driven by an independent electric motor; light sensor on the front
- The more light that hits the sensor, the faster the motor runs.
- Vehicle 1 (left) moves away from the light source, while Vehicle 2 (right) moves toward the light source.

What is Artificial Intelligence (AI)?

With some modifications of the vehicles, we can create *different “behavior patterns”*.

- Fifteen or so small robotic vehicles are moving on an enclosed four by four meter square surface.
- Some vehicles *form small groups* with relatively little movement
- Others move peacefully through the space and gracefully *avoid any collision*.
- Still others appear to *follow a leader*.

According to McCarthy’s definition, these robots can be *described as intelligent*. Yet Braitenberg showed that this *seemingly complex behavior* is produced by *very simple electrical circuits*, with *no real problem-solving ability*.

⇒ *McCarthy’s definition is insufficient* because AI has the goal of *solving difficult practical problems* which are surely too demanding for the Braitenberg vehicle.

Elaine Rich [Rich 1983]:

Artificial Intelligence is the study of how to make computers do things at which, at the moment, people are better.

- Still up-to-date in the year 2050!
- Humans are still better in many fields (e.g. understanding pictures, learning)!
- Computers are already better in many fields (e.g. playing chess)!

- It would be *dangerous*, however, *to conclude from Rich's definition that AI is only concerned with the pragmatic implementation of intelligent processes*.
- *Intelligent systems*, in the sense of Rich's definition, *cannot be built without a deep understanding of human reasoning and intelligent action in general*, because of which neuroscience is of great importance to AI.
- This also shows that the other cited definitions reflect important aspects of AI.
- A particular strength of human intelligence is *adaptivity*.
- We are capable of adjusting to various environmental conditions and change our behavior accordingly through *learning*.
- Precisely because our learning ability is so vastly superior to that of computers, *machine learning* is, according to Rich's definition, a central subfield of AI.

What is Artificial Intelligence (AI)?

Brain Science and Problem Solving

Different approaches:

- How does the human brain work?
- Problem oriented: building intelligent agents!
- A “general store” of many tools (no single universal method).

As in medicine, there is *no universal method for all AI applications*, but many solutions for diverse everyday problems, big and small.

Alan Turing defined an *intelligent machine* as one that passes the following test.

Figure: *Turing test*: one test consists of *many runs*, each with a *different tester*. In each run the tester spends five minutes typing questions to someone hidden on the other side of the wall — *a person or a machine* — and must then say which it was. The machine *passes* if *at least 30%* of the testers take it for a person.

- In the 1930s Kurt Gödel, Alonzo Church, and Alan Turing laid important foundations for logic and TCS.
- Of particular interest for AI are Gödel's theorems
 - Every logically valid statement that can be formulated in first-order predicate logic is provable using the rules of a formal calculus.
 - In higher-order logics¹, there exist true statements that are unprovable.
- Alan Turing proved the *undecidability of the halting problem*.
 - There is no program that can decide whether a given arbitrary program (and its respective input) will run in an infinite loop.
- In the 1940s, based on results from neuroscience, McCulloch, Pitts and Hebb designed the *first mathematical models of neural networks*. However, computers at that time lacked sufficient power to simulate simple brains.

¹ Higher-order logics are extensions of predicate logic, in which not only variables, but also function symbols or predicates can appear as terms in a quantification.

51

- In the 1970s, *PROLOG* was introduced as the *European counterpart to LISP*. PROLOG offers the advantage of allowing direct programming using Horn clauses, a subset of predicate logic. Like LISP, PROLOG has data types for convenient processing of lists.
- Until well into the 1980s, the string of impressive achievements in symbol processing leads to *heavy investment into the construction of intelligent computers* (e.g., Japan's *Fifth Generation Project* and Europe's *ESPRIT* program).
- For small problems, automatic provers and other symbol-processing systems sometimes worked very well. The combinatorial explosion of the search space, however, defined a very narrow window for these successes.
- Because the economic success of AI fell short of expectations, *funding for logic-based AI in the US fell dramatically during the 1980s*.

- Computer scientists, physicists, and Cognitive scientists were able to show using computers which were now sufficiently powerful, that *mathematically modeled neural networks are capable of learning using training examples, to perform tasks which previously required costly programming.*
- Such systems improve *pattern recognition*. (E.g., Facial recognition in photos and handwriting recognition.)
- In 1986: the system *Nettalk* was able to learn speech from example texts.
- Limitation: *It was usually not possible to capture the learned concept in simple formulas or logical rules.* Attempts to combine neural nets with logical rules or the knowledge of human experts met with great difficulties.

- Many diagnostic and expert systems have been built for problems of everyday reasoning using *Bayesian networks*.
 - The success of Bayesian networks stems from their intuitive comprehensibility, the clean semantics of conditional probability, and from the centuries-old, mathematically grounded probability theory.
- The weaknesses of logic, which can only work with two truth values, can be solved by *fuzzy logic*, which pragmatically introduces infinitely many values between zero and one.
- A much different path led to the *successful synthesis of logic and neural networks* under the name *hybrid systems*.
 - For example, neural networks were employed to learn heuristics for reduction of the huge combinatorial search space in proof discovery.

- Methods of *decision tree learning from data* also work with probabilities. Systems like CART, ID3 and C4.5 can quickly and automatically build very accurate decision trees which can represent propositional logic concepts and then be used as expert systems.
- Since about 1990, *data mining* has developed as a sub-discipline of AI in the area of statistical data analysis for extraction of knowledge from large databases.
 - Data mining combines techniques from databases, statistics, and machine learning, and develops scalable algorithms for extracting patterns from large datasets.

- One goal of *distributed artificial intelligence* is to use parallel computers to increase the efficiency of problem solvers.
- A very different conceptual approach results from the *development of autonomous software agents and robots that are meant to cooperate like human teams*.
 - There are many cases in which an individual agent is not capable of solving a problem, even with unlimited resources.
 - Only the cooperation of many agents leads to the intelligent behavior or to the solution of a problem.
- *Active skill acquisition by robots* is an exciting area of current research. There are robots today, for example, that independently learn to walk or to perform various motorskills related to soccer.

- The above systems offered by AI today are *not a universal recipe*, but a *workshop* with a manageable number of *tools for very different tasks*.
- Most of these tools are well-developed and are available as finished software libraries, often with convenient user interfaces.
- The selection of the right tool and its sensible use in each individual case is left to the AI developer or knowledge engineer.
- More than nearly any other science, AI is *interdisciplinary*, for it draws upon interesting discoveries from such diverse fields as logic, operations research, statistics, control engineering, image processing, linguistics, philosophy, psychology, and neurobiology.

- Research on neural networks dates back to the very beginning of AI, but the great breakthrough was long delayed: *object recognition in images* could not be solved for many years.
- This changed rapidly between *2006 and 2016*: researchers found a handful of tricks that allowed them to successfully *train backpropagation networks with more than three layers* of neurons.
- Advances in object recognition, together with progress in localization, planning, and control, helped advance autonomous systems such as service robots and self-driving vehicles.
- Deep learning also shows strong results in *medicine*: for some image-based diagnostic tasks (e.g., MRI and CT scans), carefully validated systems can match or sometimes exceed clinicians' performance.

- In January 2016, the *World Economic Forum* projected a net loss of about *5.1 million jobs* across 15 major economies from 2015 to 2020: 7.1 million jobs lost and about 2 million gained, due to the Fourth Industrial Revolution and other socio-economic, geopolitical, and demographic changes.
- AI has been one of the most important drivers of this automation trend since about 2010.

The social impact of AI is therefore a question every future AI developer must engage with.

The purpose of AI

- AI saves energy
- AI saves time
- AI saves money
- AI increases productivity

The road to paradise?

- Many unpleasant (physically hard, dirty, unhealthy) jobs can be done faster, more precisely, and above all cheaper by machines.
- Thus automation is a complete blessing for humanity, assuming it does not result in negative side effects, such as harm to the environment.
- We have to do less and less unpleasant work and in turn have more time for the good things in life.

Not necessarily!

- Some workers still face long hours, stress, and burnout, and in some OECD countries real labour income has not kept pace with productivity growth.
- One explanation is that competitive pressure can push companies to lower production costs and reduce employment.
- To maintain sales, more products must be manufactured and sold, fueling the need for continuous economic growth.
- In a country in which the population is no longer growing, this means each citizen must consume more, driving the creation of new markets and aggressive marketing.
- The growth/consumption spiral is seen as necessary for prosperity but leads to negative consequences.
 - A strong focus on wealth and possessions is associated with lower well-being; experiments also find that materialistic cues can reduce well-being.
 - Bad effects on our living conditions. (We are over-exploiting nature's nonrenewable resources.)

Where do the profits go?

- Not to the workers!
- Part of the profits is spent on investment and further growth.
- The rest is taken by the capital owners.

What is missing is a fair and just distribution of profits. How can this be achieved?

- Change the rules and laws of the economy so that all people profit from increased productivity.

AI in transportation: Autonomous vehicles, such as self-driving cars and robotaxis; electric self-driving cars are one example.

■ Pros:

- Comfort and convenience.
- Reducing in the number of cars and places for parking.
- More environmentally friendly than current vehicles.
- Increase safety.

■ Cons:

- Taxi-driving jobs may be displaced or transformed.
- Rebound effect: Shorter driving time + comfortable, cheap driving $\Rightarrow$ Driving more.
- Security. (Hackers can manipulate the vehicles' controls through security holes in their network protocols.)

Service robots are being developed for household and assistance tasks. The assistance robot *Marvin* is one research example; Boston Dynamics' *Atlas* is an industrial humanoid robot.

■ Pros:

- A large gain in comfort (e.g., a robot that cleans and tidies without complaint).
- Assistance robots could support the *elderly* and people with disabilities — increasingly important in the coming demographic shift.

■ Cons:

- Potential trade-offs: service robots may create additional demand for natural resources and energy.
- General-purpose humanoid robots could be misused, including for military purposes.

⇒ We should engage in social discourse before such robots reach the market.

Agent denotes rather generally *a system that processes information and produces an output from an input.*

Reflex Agents only react to input. (Representing a function from the set of all inputs to the set of all outputs. Useful in problems involving the Markov decision process.)

Agents with memory can also include the past in their decisions. (Not representing a function. The same input may lead to different outputs because of the past memory.)

Goal-based Agents act depending on the goal.

Learning Agents are capable of changing themselves given training examples or through positive or negative feedback, such that the average utility of their actions grows over time.

Distributed Agents the intelligence are not localized in one agent, but rather can only be seen through cooperation of many agents.

Example 1 (Spam filter)

A *spam filter* is an agent that puts incoming emails into wanted or unwanted (spam) categories, and deletes any unwanted emails.

Agent 1:

		correct class	
		wanted	spam
spam filter decides	wanted	189	1
	spam	11	799

Agent 2:

		correct class	
		wanted	spam
spam filter decides	wanted	200	38
	spam	0	762

Which agent is better?

- *Agent 1 makes fewer errors than Agent 2*: out of the same set of 1000 emails, Agent 1: 12 errors, Agent 2: 38 errors.
- *But those fewer errors may be severe*: the user loses 11 potentially important emails.
- Because there are in this case *two types of errors of differing severity*, each error should be *weighted with the appropriate cost factor*.

Cost-based Agents

The goal of a *cost-based agent* is to *minimize the long-term cost (i.e. the average cost) caused by wrong decisions*. The sum of all weighted errors results in the total cost.

- Example: The medical diagnosis system LEXMED.

Utility-based Agents

The goal of a *utility-based agent* is to *maximize the utility derived from correct decisions in the long term*, that is, on average. The sum of all decisions weighted by their respective utility factors gives the total utility.

Exercise 4 ([Ertel 2025], Exercise 1.6, p. 23)

- (a) Determine for both agents in the spam filter example the costs created by the errors and compare the results. Assume here that having to manually delete a spam email costs one cent and retrieving a deleted email, or the loss of an email, costs one dollar (= 100 cents).
- (b) Determine for both agents the profit created by correct classifications and compare the results. Assume that for every desired email recognized, a profit of one dollar accrues and for every correctly deleted spam email, a profit of one cent.

Agent 1:

		correct class	
		wanted	spam
spam filter decides	wanted	189	1
	spam	11	799

Agent 2:

		correct class	
		wanted	spam
spam filter decides	wanted	200	38
	spam	0	762

Environment:

observable the agent always knows the complete state of the world. (E.g., chess computer.)

partially observable the agent does not always know the complete state of the world. (E.g., robot.)

deterministic the current state and the action(s) taken determine exactly one next state. (E.g., 8-puzzle.)

nondeterministic the same current state and action(s) can lead to more than one possible next state. (E.g., a robot action with uncertain outcomes.)

discrete state, time, percept, and action variables take values in finite or countably infinite sets. (E.g., chess.)

continuous at least one state, time, percept, or action variable varies over a continuous range. (E.g., position, speed, or steering angle in driving.)

Exercise 5 ([Ertel 2025], Exercise 1.4, p. 23)

- (a) Why is a deterministic agent with memory not a function from the set of all inputs to the set of all outputs, in the mathematical sense?
- (b) How can one change the agent with memory, or model it, such that it becomes equivalent to a function but does not lose its memory?

Exercise 6 ([Ertel 2025], Exercise 1.5, p. 23)

Let there be an agent with memory that can move within a plane. From its sensors, it receives at clock ticks of a regular interval Δt its exact position (x, y) in Cartesian coordinates.

- (a) Give a formula with which the agent can calculate its velocity from the current time t and the previous measurement of $t - \Delta t$.
- (b) How must the agent be changed so that it can also calculate its acceleration? Provide a formula here as well.

Knowledge Engineering: How to get the knowledge into the AI system?

- knowledge sources: human experts, the knowledge engineer, and databases.
- machine learning: learning from data or experience, including examples, observations, feedback, and active exploration.

Separation of knowledge and inference

- The same inference mechanism can often be reused across applications that use the same knowledge-representation framework.
- Knowledge can be stored declaratively. (In the knowledge base there is only a description of the knowledge, which is independent from the inference system in use.)
- *Concrete payoff*: adapting a medical expert system to another disease can be easier: revise or replace the knowledge base and reuse the inference engine when the new knowledge fits the same framework.

Knowledge Representation with formal languages

- Propositional logic.
- First-order predicate logic (shortly: PL1).
- Probabilistic logic.
- Decision trees.

Knowledge-Based Systems

- *Watson* (IBM) is a question-answering software agent: it is fed clues in natural language and returns answers.
- Its knowledge base comprises about *four terabytes*, including the full text of Wikipedia. Watson was built in IBM's *DeepQA* project, combining natural language processing, information retrieval, machine learning, knowledge representation and reasoning, and massively parallel computation.
- In February 2011, Watson defeated the human champions Brad Rutter and Ken Jennings on the quiz show “Jeopardy!”.
- Watson’s fast responses relied on a massively parallel *DeepQA* architecture and *90 IBM Power 750 servers* with *2,880 POWER7 processor cores*.
